

5) To call the constructor of super class : **Constructor Chaining**  
Whenever we write a class in java and we don't write any kind of constructor in the class then the java compiler will automatically add a default no-argument constructor to the class.  
The default constructor (no-argument constructor) is added only if there is no explicit constructor of the class. If there is an explicit constructor of the class then the java compiler will not add a default constructor to the class.  
In the first line of any constructor of any class (either super or this) then the java compiler will automatically add a call to the constructor of the super class.  
Now the purpose of this chapter is to show you how to call the constructor of the super class or the no-argument constructor of the super class.  
In order to call the constructor of super class as well as some class, we have used 4 cases.  
Case 1:  
Example 1:  
In this example, we have a class named 'Student' and it has a constructor 'Student()' and a constructor 'Student(int id, String name)'.  
In the first line of the constructor 'Student()' we have written 'super()' to call the constructor of the super class.  
In the first line of the constructor 'Student(int id, String name)' we have written 'super(id, name)' to call the constructor of the super class.  
Case 2:  
Example 2:  
In this example, we have a class named 'Student' and it has a constructor 'Student()' and a constructor 'Student(int id, String name)'.  
In the first line of the constructor 'Student()' we have written 'super()' to call the constructor of the super class.  
In the first line of the constructor 'Student(int id, String name)' we have written 'super(id, name)' to call the constructor of the super class.  
Case 3:  
Example 3:  
In this example, we have a class named 'Student' and it has a constructor 'Student()' and a constructor 'Student(int id, String name)'.  
In the first line of the constructor 'Student()' we have written 'super()' to call the constructor of the super class.  
In the first line of the constructor 'Student(int id, String name)' we have written 'super(id, name)' to call the constructor of the super class.  
Case 4:  
Example 4:  
In this example, we have a class named 'Student' and it has a constructor 'Student()' and a constructor 'Student(int id, String name)'.  
In the first line of the constructor 'Student()' we have written 'super()' to call the constructor of the super class.  
In the first line of the constructor 'Student(int id, String name)' we have written 'super(id, name)' to call the constructor of the super class.
